POZI CODING CHALLENGE

Pozi is a Web GIS map tool. One of the core functionalities is to be able to display a map, and given a location, show you where it is on a map, and from different data sources, show information about the point of interest.

For this coding challenge, create a simple web application that:

1. Lets a user enter a place, address, or landmark
2. Shows the user where it is on the map. For example, if this app is marketed in Australia, it should show them a relevant result in Australia
3. Show any useful information about that place. For example, if a user searches "Melbourne Town Hall", it might show them the link to its website
4. Allows the application to be launched and operated via URL. For example, a user might be able to view a place or do a search straight from the browser's address bar.

Some resources you may find helpful:

1. <https://nominatim.org/release-docs/develop/api/Overview/>
2. <https://leafletjs.com/examples/quick-start/>

When coding, some but not all things you should aim for:

1. Clean, readable and maintainable code
2. Production quality, e.g. Imagine that you are part of a bigger team, and that your team will maintain and expand on your work

You are not limited to any language or framework to implement this, but at Pozi we use a combination of JavaScript, TypeScript, and React to build our web applications.

Use `git` for source control - commit small changes, will help us see your approach tackling this problem. Include the `.git` directory along with any source files in an archived `zip` file you send back. Include a README file with instructions on how to build and run it, and if available online provide a link.
